AN ANALYSIS FOR COOPETITION AMONG MARKET PARTICIPANTS FOR THE CREATION
AND MAINTENANCE OF A CONSORTIUM GOVERNED SATELLITE NETWORK
INFRASTRUCTURE.**Abstract**

There is a rising trend in providing storage via decentralised networks managed with token based incentive mechanisms by protocols such as IPFS, FileCoin, Estuary and more . This storage space is analogous to the satellite-imagery provided by Constellations such as Maxar . The creation and maintenance of such constellations can cost upto 600 million dollars according to Tony Frazier , a maxar executive . Therefore we require a cooperative model that reduces costs , development and maintenance of such networks all while market participants attempt to break-even and profit . This paper wishes to analyse and identify the possible incentive mechanisms for the creation and maintenance of such networks, required protocol-consensus among market participants and possible hurdles within such a process. Furthermore, the paper wishes to demonstrate the possible results of such cooperation. It concludes that under these conditions cooperation strategy is necessary and beneficial.
